A Reminder about Finding P-values. In a hypothesis test, the P-value is based on the assumption that the null hypothesis is true. But the P-value is also related.

Define p_1 and p_2 to be the proportions of all teens who improve when taking Fluoxetine and placebo, respectively, with psychiatric treatment. We amass evidence for this statement by conducting a statistical sample. As the result shows, within the Aboriginal student population, 38 students are female. The P-value comes from a normal model of the sampling distribution of difference. It is twice the area of the smaller tail defined by the test statistic. Check the Normality Criteria Determine if a normal model is a good fit for the sampling distribution. Since we have a two-tailed test the P-value is the probability that the z-score is greater than 2 or less than -2. It means that if there is no difference in the population proportions, there is about a 4.
